LONDINI,

Jussu Societatis Regie ac Typis Josephi Streater. Prostat apud  
plures Bibliopolas. Anno MDCLXXXVII.

«Our **water**, if the earth were located in the orbit of Saturn, would be **frozen**, if in the orbit of Mercury it would depart at once into **vapours**. For the light of the sun, to which the heat is proportional, is seven times denser in the orbit of Mercury than with us: and with a thermometer I have found that with a seven-fold increase in the heat of the summer sun, water boils off.»

— Newton, 1687

## earth's energy *budget*

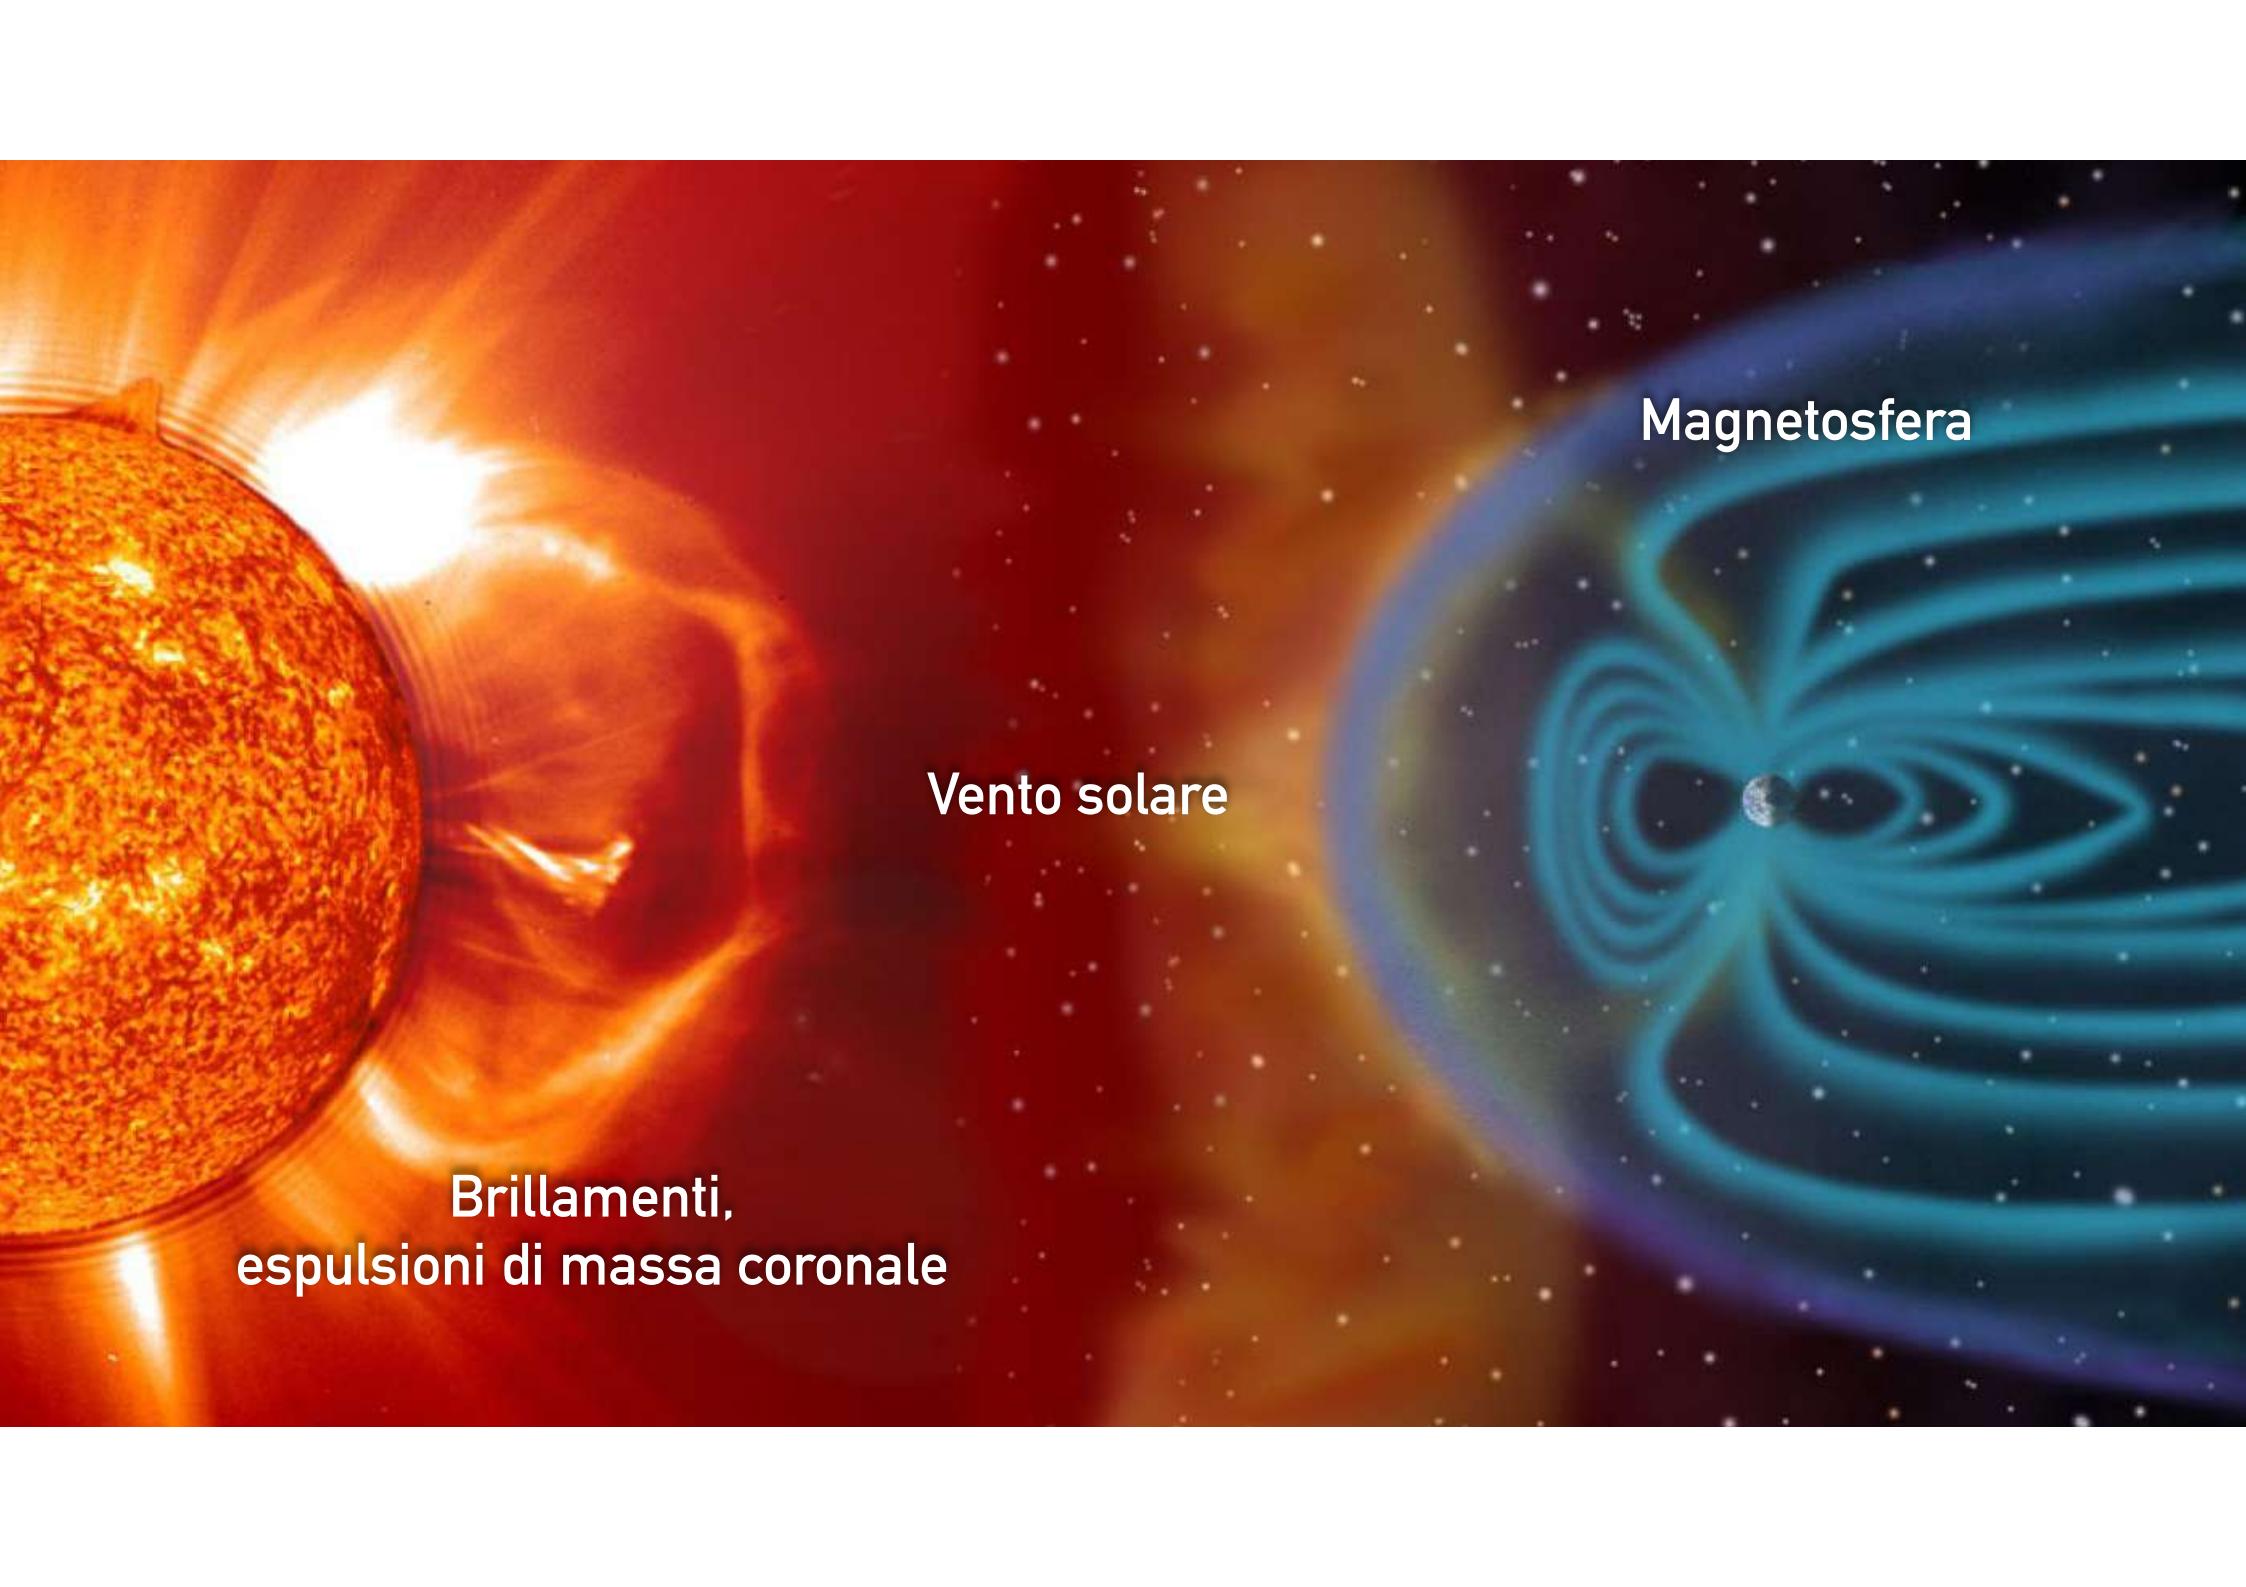

The Earth's energy budget describes the various kinds and amounts of energy that enter and leave the Earth system. It includes both radiative components (**light** and **heat**), that can be measured by CERES, and other components like conduction, convection, and evaporation which also transport heat from Earth's surface. On average, and over the long term, there is a balance at the top of the atmosphere. The amount of energy coming in (**from the sun**) is the same as the amount going out (**from reflection of sunlight** and from **emission of infrared radiation**).

All values are fluxes in  $\text{W m}^{-2}$   
and are average values based on ten years of data
